Advanced Recursion

Steps Revisited:

1.Base Case:

First try to make a base case in order to set up a termination condition.

2. Edge Case (Optional):

This is used to avoid accessing array at the outliers.

3. Solving Smaller Sub-Problem:

Relax, this will be taken care by the recursive call. :)

4. Solving the Final Step:

Recall PMI, we have to work on our final step of calling.

As we can see, the output should be 3.

Minimum Cost Path

Given an integer matrix of size m*n, you need to find out the value of minimum cost to reach from the cell (0, 0) to (m-1, n-1).

From a cell (i, j), you can move in three directions : (i+1, j), (i, j+1) and (i+1, j+1). Cost of a path is defined as the sum of values of each cell through which path passes.

Input Format:

Line 1: Two integers, m and n

Next m lines: n integers of each row (separated by space)

Output Format:

Minimum cost

Constraints:

1 <= m, n <= 20

Lowest Common Subsequence

A subsequence is a sequence that can be derived from another sequence by deleting some elements without changing the order of the remaining elements. Longest common subsequence (LCS) of 2 sequences is a subsequence, with maximal length, which is common to both the sequences.

Given two strings, S and T, find the value of longest common subsequence and print it as a line of space-separated integers.

Input Format

The first line contains two space separated integers n and m, the sizes of sequences S and T.

The next line contains string S.

The next line contains string T.

Constraints

1<= n <= 100 1<= m <= 100

Output Format

Print the length of the longest common subsequence as a string on one line.

Sample Input

5 6 abcde cadbce

Sample Output

4

Explanation

The longest common subsequence is "abce" so the length is 4.
